

Deployment Models of Cloud Computing

1. Public Cloud

- * Multi-tenant (IBM, HCL, Myntra, Azure, AWS, GCP)
- * Shared Hardware
- * Resources isolated by virtualization
- * Cost effective (Cheaper)

*Accessible over the Internet**

2. Private Cloud

- * Single-tenant (Dedicated to one organization)
- * Reserved Hardware (On-premises or hosted)
- * More secure & isolated
- * Costly (high investment)

*Accessible over the Intranet**

3. Hybrid Cloud

*Combination of Public + Private Cloud**

- * Single-tenant + Shared resources both possible
- * Reserved + Shared Hardware mix

*Accessible via Internet + Intranet**

- * Useful for data security + scalability

Public Cloud – Ye sabse common hai. Azure, AWS, GCP jaise vendors shared hardware dete hain jisme multiple companies ek hi physical hardware pe apna alag-alag VM chala rahi hoti hain. Ye cheap hota hai aur easily Internet se accessible hota hai. Example: Gmail, Office 365.*

Private Cloud – Ye ek hi company ke liye hota hai. Matlab hardware aur resources reserved hote hain, jo ya to company ke own data center me hote hain ya kisi vendor ke dedicated environment me. Ye zyada secure hota hai but costly bhi hota hai. Example: Banking companies apna private cloud rakhti hain.*

Hybrid Cloud – Ye dono ka mix hai. Sensitive data private cloud me aur scalable workloads public cloud me rakhe jaate hain. Isse flexibility milti hai. Example: E-commerce companies*

(order details public cloud me, payment data private cloud me).
